bezierplot

Linus Romer

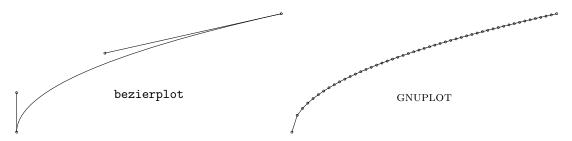

April 12, 2018

1 Introduction

bezierplot is as well a Lua program as a (Lua)LATEX package. This document describes both

Given a smooth function, bezierplot returns a smooth bezier path written in TikZ notation (which also matches METAPOST) that approximates the graph of the function. For polynomial functions of degree ≤ 3 and inverses of them, the approximation is exact. bezierplot finds special graph points such as extreme points and inflection points and reduces the number of used points.

The following example will show a comparison of GNUPLOT with bezierplot for the function $y = \sqrt{x}$ for $0 \le x \le 5$:

GNUPLOT used 51 samples (no smoothing) and is still quite inexact at the beginning, whereas bezierplot uses 4 points only and is exact!

2 Installation

As bezierplot is written in Lua, the installation depends if you are using LuaLATEX or another LATEX engine.

2.1 Installation For LuaLATEX

If you have installed bezierplot by a package manager, the installation is already complete. The manual installation bezierplot is done in 2 steps:

- copy the files bezierplot.lua and bezierplot.sty somewhere in your texmf tree (e.g. to ~/texmf/tex/lualatex/bezierplot/bezierplot.sty and ~/texmf/scripts/bezierplot/bezierplot.lua)
- update the ls-R databases by running mktexlsr

2.2 Additional Installation Steps For Other LATEX Engines

You will have to call bezierplot as an external program via the option --shell-escape (--write18 for MiKTEX). Therefore, bezierplot.lua has to be copied under the name bezierplot to a place, where your OS can find it. Under Linux this usually means copying to /usr/local/bin/, but for Windows this will probably include more steps (like adding to

the PATH). Of course, Lua has to be installed as well. As soon as you can call bezierplot from a command line (e.g. by typing bezierplot "x^2"), it should also work with other LATEX engines.

3 Loading

The bezierplot package is loaded with \usepackage{bezierplot}. There are no loading options for the package.

4 Usage

A minimal example of LuaLATEX document could be:

\documentclass{article}
\usepackage{tikz,bezierplot}
\begin{document}
\tikz \draw \bezierplot{x^2};
\end{document}

The command \bezierplot has 4 optional arguments in the sense of

\bezierplot[XMIN][XMAX][YMIN][YMAX]

The defaults are XMIN = YMIN = -5 and XMAX = YMAX = 5.

You may reverse the graph by making XMIN bigger than XMAX. E.g.

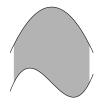

\bezierplot[-5][5]{0.5*x+1}

returns (-5,-1.5) -- (5,3.5), whereas

 $\begin{tabular}{l} \begin{tabular}{l} \begin{tabu$

returns the reversed path (5,3.5) -- (-5,-1.5). This is useful, if you want to cycle a path to a closed area:

```
\begin{tikzpicture}
\fill[black!30] \bezierplot[-1][1]{2-x^2}
-- \bezierplot[1][-1]{x^3-x} -- cycle;
\draw \bezierplot[-1.1][1.1]{2-x^2};
\draw \bezierplot[-1.1][1.1]{x^3-x};
\end{tikzpicture}
```

4.1 Running Raw bezierplot

Of course, you can run bezierplot.lua in a terminal without using LATEX, e.g.

lua bezierplot.lua "3*x^0.8+2"

will return

```
(0,2) ... controls (0.03,2.282) and (0.268,3.244) ... (1,5) You can set the window of the graph as follows: lua bezierplot.lua "FUNCTION" XMIN XMAX YMIN YMAX e.g. lua bezierplot.lua "FUNCTION" 0 1 -3 2.5 will set 0 \le x \le 1 and -3 \le y \le 2.5. You may also omit the y-range, hence lua bezierplot.lua "FUNCTION" 0 1 will set 0 \le x \le 1 and leave the default -5 \le y \le 5.
```

4.2 Notation Of Functions

The function term given to bezierplot must contain at most one variable: x (e.g. "2.3*(x-1)^2-3"). You must not omit * operators:

```
wrong: 2x(x+1) correct: 2*x*(x+1)
```

You have two possibilities to write powers: " x^2 " and "x**2" both mean x^2 .

The following functions and constants are possible:

```
absolute value (remember: your function should still be smooth)
        \cos^{-1} inverse function of cosine in radians
acos
        \sin^{-1} inverse function of sine in radians
asin
        \tan^{-1} inverse function of tangent in radians
        cube root 3/ that works for negative numbers, too
cbrt
        cosine for angles in radians
cos
        the exponential function e^{()}
exp
        the euler constant e = \exp(1)
        the natural logarithm \log_e()
log
        Archimedes constant \pi \approx 3.14
рi
        sign function
sgn
        sine for angles in radians
sin
        square root \sqrt{\phantom{a}}
sqrt
        tangent for angles in radians
tan
```

5 Examples of bezierplot in Comparison with gnuplot

The following graphs are drawn with bezierplot (black) and GNUPLOT (red). GNUPLOT used 1000 samples per example. The functions are given below the pictures (left: bezierplot, right: GNUPLOT).
